

PILOT STUDY REVEALS...

NEW WEAPON AGAINST LYME BORRELIOSIS

A Disease Linked to Over 300 Medical Conditions

An 8-month pilot study was recently conducted with 28 patients suffering from Advanced Chronic Lyme borreliosis. All the patients tested positive for Lyme borreliosis utilizing the Western Blot blood

test for *Borrelia burgdorferi*, the bacteria that causes Lyme disease. The control group was treated with antibiotics, and at the end of the study, from 14 patients in the group, 3 improved slightly, 3 got worse and the rest remained with no change in their clinical condition. The experimental group was treated with Samento (Pentacyclic

Alkaloid Chemotype *Uncaria tomentosa*). At the end of the study 85% of the patients in this group tested negative for *Borrelia burgdorferi*, and all the patients experienced a dramatic improvement in their clinical condition. A full report will be available soon.

SAMENTO® Medical Breakthrough

Samento, also known as TOA-Free Cat's Claw, is a rare chemotype of a medicinal plant commonly known as Cat's Claw, botanical name *Uncaria tomentosa*. Unlike traditional Cat's Claw products, this chemotype does not contain a group of chemical antagonists called tetracyclic oxindole alkaloids (TOAs) that act upon the central nervous system and can greatly inhibit the positive effect of the pentacyclic oxindole alkaloids (POAs). Samento contains a standardized amount of (POAs) that primarily affect the immune cells responsible for non-specific and cellular immunity, and demonstrate powerful immune system modulating properties. According to research conducted in Austria, traditional Cat's Claw products may contain as much as 80% TOAs, and as little as 1% TOAs can cause a 30% reduction in immune system modulating properties that POAs provide.

NEW FINDINGS ON LYME BORRELIOSIS

History of the Disease

Lyme disease was first recognized in the United States in 1975, following a mysterious outbreak of juvenile rheumatoid arthritis near the community of Lyme, Connecticut. The rural location of the Lyme outbreak and the onset of illness during summer and early fall suggested that the transmission of the disease was by an arthropod vector.

In 1982, the etiologic agent of Lyme disease was discovered by Willy Burgdorfer. Burgdorfer isolated spirochetes belonging to the genus *Borrelia* from the mid-guts of Ixodes ticks. He showed that these spirochetes reacted with immune serum from patients that had been diagnosed with Lyme disease. Consequently, the Lyme spirochete resembling the syphilis spirochete was given the name *Borrelia burgdorferi*.

Prevalent on 6 Continents

Lyme disease, known as Lyme Borreliosis in much of the world, is prevalent on 6 continents and recognized as an epidemic in many countries. Samento has been available to the public in Bulgaria, where a high incidence of Lyme disease exists, since January 2001. Within 2 months it became the most widely sold natural medicine in that country. Dr. Atanas Tzonkov, director of Bulgaria's largest private medical clinic, has treated thousands of patients with Samento. He reports that it has been used successfully to treat over 100 conditions. A possible theory is that most of these conditions were actually misdiagnosed Lyme disease or Lyme disease was a component of the illnesses that the patient was suffering from.

Methods of Transmission

W.T. Harvey, MD, MS, MPH and Patricia Salvato, MD of Diversified Medical Practices in Houston, Texas recently published the article- *Lyme disease: Ancient Engine of an Unrecognized Borreliosis Pandemic*. They were puzzled by the high number of patients testing positive for Lyme disease. Many of these patients presented with "established" criteria for Lyme disease, but others did not. The fact that southeastern Texas is a 'non-endemic' region, and that many of the patients had no history of erythema migrans rash, led the doctors to question established methods for Lyme disease consideration. Careful reflection of published research leads them to conclude the following. First, the arthropod is not the exclusive vector of Lyme disease. In addition to ticks, *Borrelia burgdorferi* may be carried and transmitted by fleas, mosquitos, and mites. Second, Lyme disease is not exclusively vector-borne. Compelling evidence supports horizontal (sexual) and vertical (congenital) human to human transfer.

“Compelling evidence supports... human to human transfer.”

Other front-line physicians are arriving at the same conclusions. “Of the more than 5,000 children I've treated, 240 have been born with the disease,” says Charles Ray Jones, MD. Dr. Jones, who is the world's leading pediatric specialist on Lyme Disease, says that about 90% of his practice is comprised of patients with the disease. He also states, “Twelve children who've been breast-fed have subsequently developed Lyme”.

University of Wisconsin researchers state that dairy cattle and other food animals can be infected with *B. burgdorferi* and hence some raw foods of animal origin might be contaminated with the pathogen. Recent findings indicate that the pathogen may be transmitted orally to laboratory animals, without an arthropod vector. Thus, the possibility exists that Lyme disease can be a food infection.

Citing limitations of laboratory tests for the detection of antibodies to *Borrelia*, a study was conducted in 1995 at the University of

— Continued on page 3

Vienna (Austria) for the detection of *Borrelia*. Utilizing polymerase chain reaction testing for DNA, *Borrelia* was found to be present in both the urine and breast milk of patients previously diagnosed with Lyme disease. A study conducted at the Sacramento (California) Medical Foundation Blood Center in 1989 states that there is evidence that the transmission of *Borrelia* is possible by blood transfusion. Furthermore, in 1990, a study by the Centers for Disease Control (CDC) in Atlanta, Georgia stated that the data demonstrates that *Borrelia burgdorferi* can survive the blood processing procedures normally applied to transfused blood in the USA.

Dormancy and Activation

It is believed that years can pass before symptoms appear in a patient that has been infected with *Borrelia*. In 1998, a study conducted in Switzerland demonstrated that only 12.5% of the patients that tested positive for *Borrelia* developed clinical symptoms confirming that *Borrelia burgdorferi* infection is often asymptomatic. A report from Germany outlines the case of a 12 year old boy that developed Lyme Arthritis 5 years after being bit by a tick. The case indicates that the latency period between tick bite and onset of Lyme Arthritis may last up to 5 years.

All asymptomatic carriers of *Borrelia* are at risk of developing Lyme disease at some point. Stress, an increasing health concern for physicians worldwide, may have been the trigger that activated Lyme disease in a patient in Sweden. The case is reported of a 26 year old woman with latent Lyme borreliosis that was concurrently activated with a herpes simplex virus type 1 infection. Immune suppression by stress may have caused activation of both infections.

Number of Cases

Lyme disease is the fastest-growing epidemic in the world. The Center for Disease Control (CDC) in Atlanta, Georgia, U.S.A. affirms that "there is considerable underreporting" of Lyme disease, maintaining that the actual infection rate may be 1.8 million, 10 times higher than the 180,000 cases currently reported. Nick Harris, Ph.D., Director of the International Lyme and Associated Diseases Society (ILADS), states "Lyme is grossly under-reported. In the U.S., we probably have about 200,000 cases per year." Dan Kinderleher, MD an expert on Lyme disease, stated on the Today Show on June 10, 2002 that the number of cases may be 100 times higher (18 million in the United States alone) than reported by the CDC.

Jo Anne Whitaker, MD has developed a "Rapid Identification of *Borrelia burgdorferi*" and has over 3200 positive specimens for *Borrelia burgdorferi* from forty-six (46) states, including Alaska and Hawaii. In addition, Dr. Whitaker has had positive specimens from Australia, Canada, Canary Islands, Brazil, Denmark, England, France, Germany, Ireland, Netherlands, Scotland, Spain, Sweden and Switzerland.

Considering vector, congenital and sexual transfer, Dr. Harvey and Dr. Salvato estimate that 15.5% of the global population, nearly 1 billion people, could be infected with *Borrelia*.

Lee Cowden, MD states that there are very few symptoms where one should not consider Lyme, especially given that a quarter of the U.S. population may be affected. It is estimated that Lyme disease may be a contributing factor in more than 50% of chronically ill people.

The Sierra Integrative Medicine Clinic in Reno, Nevada, states that "Authorities estimate that up to 90 percent of the population could be carrying the Lyme spirochete and that Lyme is a factor in over 50 percent of chronic illnesses."

300 MEDICAL CONDITIONS RELATED TO LYME BORRELIOSIS

Frequently Misdiagnosed

Katrina Tang, M.D., HMD, founder and Director of Research at the Sierra Integrative Medicine Clinic in Reno, Nevada, states that Lyme disease eludes many doctors because of its ability to mimic many other diseases. According to an informal study conducted by the American Lyme disease Alliance (ALDA), most patients diagnosed with Chronic Fatigue Syndrome (CFS) are actually suffering from Lyme disease. In a study of 31 patients diagnosed with CFS, 28 patients, or 90.3%, were found to be ill as a result of Lyme.

Dr. Paul Fink, past president of the American Psychiatric Association, has acknowledged that Lyme disease can contribute to every psychiatric disorder in the Diagnostic Symptoms Manual IV (DSM-IV). This manual is used to diagnose psychiatric conditions such as attention deficit disorder (ADD), antisocial personality, panic attacks, anorexia nervosa, autism and Aspergers syndrome (a form of autism) to name a few.

List of Conditions

Lyme Borreliosis causes, mimics, is manifested as, is misdiagnosed as or is a contributing factor to many conditions. The following list of over 300 conditions was compiled by means of a non exhaustive search of published scientific literature and includes:

Abdominal pseudo-eventration,	Attention Deficit Disorder (ADD)	Chronic muscle weakness
Acrodermatitis chronica atrophicans (ACA)	Attention Deficit Hyperactivity Disorder (ADHD)	Chronic urticaria
Acute Acral Ischemia	Bannwarth's Syndrome	Cerebellar ataxia
Acute conduction disorders	Behcet's disease	Cogan's syndrome
Acute coronary syndrome	Bell's Palsy	Collagenosis
Acute exogenous psychosis	Benign cutaneous lymphocytoma	Complete flaccid paraplegia
Acute meningitis	Benign lymphocytic infiltration (Jessner-Kanof)	Complex Regional Pain Syndrome (CRPS)
Acute myelo-meningo-radiculitis	Bilateral carpal tunnel syndrome	Concomitant neuroretinitis
Acute peripheral facial palsy	Bilateral facial nerve palsy	Conduction disorder
Acute perimyocarditis	Bilateral follicular conjunctivitis	Conus medullaris syndrome
Acute pyogenic arthritis	Bilateral keratitis	Coronary aneurysm
Acute reversible diffuse conduction system disease	Bilateral papilloedema	Cortical blindness
acute transitory auriculoventricular block	Biphasic meningoencephalitis	Coxitis
Acute transverse myelitis	Bipolar Disorder	Cranial Neuritis
Acute urinary retention	Brain Tumor	Cranial polyneuritis
Acquired Immune Deficiency Syndrome (AIDS)	Brown recluse spider bite	Craniopharyngioma
Algodystrophy	Brown-Sequard syndrome	Cutaneous B-cell lymphoma
Allergic conditions	Cardiac Disease	Dementia
Allergic conjunctivitis	Cardiomegaly	Demyelinating disorders
Alopecia	Cardiomyopathy	Depression
Alzheimer's Disease	Carditis	Dermatomyositis
Amyotrophic lateral sclerosis (ALS - Lou Gehrig's Disease)	Carpal tunnel syndrome	Diaphragmatic paralysis
Amyotrophy	Catatonic syndrome	Diffuse fasciitis
Anamnesis	Cauda equina syndrome	Dilated cardiomyopathy
Anetoderma	Central vestibular syndrome	Diplopia
Anorexia nervosa	Cerebellitis	Discopathy
Antepartum fever	Cerebral atrophy	Disseminated choroiditis
Anxiety	Cerebro-vascular disease	Dorsal epiduritis
Arrhythmia	Cervical facet syndrome	Encephalitis
Arthralgia	Cheilitis granulomatosa	Encephalomyelitis
Arthritis	Chiasmal optic neuritis	Encephalopathy
Asymmetrical hearing loss	Chorea	Endogenous paranoid-hallucinatory syndrome
Atraumatic spontaneous hemarthrosis	Choriocapillaritis	Eosinophilia
Atrioventricular block	Chronic encephalomyelitis	Eosinophilic fasciitis (Shulman syndrome)
	Chronic Fatigue Syndrome	Epilepsy
		Epileptic crises
		Episcleritis
		Epstein Barr
		Erythema chronicum migrans
		Exanthema (local and generalized)
		Extrapyramidal disorders

— Continued on page 5

List of Conditions (continued)

Facial diplegia
 Fascicular tachycardia
 Fatal adult respiratory distress syndrome
 Fetal death
 Fever
 Fibromyalgia
 Fibrositis
 Focal nodular myositis
 Frontotemporal atrophy
 Generalised motor neuron disease
 Genuiculata neuralgia
 Giant cell arteritis
 Gonarthrits
 Granuloma annulare
 Guillain-Barré Syndrome
 HLA-B27 negative sacroiliitis
 Headaches (severe)
 Hearing loss
 Heart block
 Hemiparesis
 Hemophagocytic syndrome
 Hepatic disorders
 Hepatitis
 Herniated discs
 Holmes-Adie syndrome
 Horner's syndrome
 Human necrotizing splenitis
 Hydrocephalus
 Hyperacusis
 Hyperbilirubinemia
 Hypothyroidism
 Idiopathic atrophoderma of Pasini and Pierini (IAPP)
 Idiopathic facial paralysis
 Infarction pain
 Impaired Brainstem response
 Infantile sclero-atrophic lichen
 Infectious Mononucleosis
 Infiltrating lymphadenosis benigna cutis
 Inflammatory cerebrospinal fluid syndrome
 Influenza
 Internuclear ophthalmoplegia
 Interstitial granulomatous dermatitis
 Intracerebral haemorrhage
 Intracranial aneurysm
 Intracranial hypertension
 Intracranial mass lesions
 Intrauterine growth retardation
 Iritis
 Irritable Bowel Syndrome
 Isolated acute myocarditis
 Isolated lymphadenopathy
 Isolated neuritis of the sciatic nerve
 Isolated oculomotor nerve paralysis
 Isolated posterior cord syndrome
 Jaundice
 Juvenile Rheumatoid Arthritis
 Keratitis
 Keratoconus
 Left sided sudden hemiparesis
 Lichen sclerosis
 Livedo racemosa
 Lofgren's syndrome
 Lupus
 Lymphadenosis benigna cutis
 Lymphocytoma cutis
 Lymphoma
 Lumboradicular syndrome
 Melkersson-Rosenthal syndrome
 Memory impairment
 Meningeal lymphoma
 Meningitis
 Meningoencephalomyelitis,
 Meningoencephalomyelorradiculoneuritis
 Meningoradiculitis
 Migraines
 Mono-arthritis
 Monolateral chorioretinitis
 Morgagni-Adams-Stokes syndrome (MAS)
 Morning glory syndrome
 Morphea
 Motor neuron syndrome
 Multiple mononeuropathy
 Multiple Sclerosis
 Myelopathy
 Myofascial pain syndrome
 Myositis
 Neonatal respiratory distress
 Neuromyotonia
 Nodular panniculitis
 Normal-pressure hydrocephalus (NPH)
 Oculomotor paralysis
 Oligoarthritis
 Opsoclonus-myoelonus syndrome
 Nodular fasciitis
 Non-Hodgkin's lymphoma
 Obsessive-compulsive disorder
 Optic atrophy
 Optic disk edema
 Organic mood syndrome
 Optic nerve lesion
 Otoneurological Disorders
 Panuveitis
 Papillitis
 Paralysis of abdominal muscles
 Paraneoplastic polyneuropathy
 Paranoia
 Parkinsonism
 Parotitis
 Pars plana vitrectomy
 Parsonage and Turner syndrome
 Peripheral facial palsy
 Peripheral neuropathy
 Peripheral vascular disorder
 Pericarditis
 Perimyocarditis
 Persistent atrioventricular block
 Pigment epitheliitis
 Polymyalgia rheumatica
 Polyneuritis cranialis
 Polyneuropathy
 Polysymptomatic autoimmune disorder
 Porphyrinuria
 Posterior scleritis
 Primary lymphoma of the nervous system
 Presenile dementia
 Progressive cerebral infarction
 Progressive facial hemiatrophy (Parry-Romberg syndrome)
 Progressive stroke
 Progressive supranuclear paralysis
 Prolonged pyrexia
 Propriospinal myoclonus
 Pseudo tumor Cerebrae
 Pseudolymphoma
 Pseudoneoplastic weight loss
 Psychosomatic disorders
 Radiculoneuritis
 Ramsay Hunt syndrome (pleocytosis)
 Raynaud's syndrome
 Recurrent paralysis
 Reflex sympathetic dystrophy
 Reiter's Syndrome
 Respiratory failure
 Restless legs syndrome
 Retinal pigment epithelium detachment
 Retinal vasculitis
 Reversible dementia
 Rheumatic Fever
 Rheumatoid Arthritis
 Rhombencephalitis
 Sacro-iliitis infection
 SAPHO syndrome
 Sarcoidosis
 Schizophrenia
 Schoenlein-Henoch purpura
 Scleroderma
 Secondary syphilis
 Seizure Disorders
 Sensorineural Hearing Loss
 Septal panniculitis
 Septic arthritis
 Seventh nerve paralysis
 Sick sinus syndrome
 Spontaneous brain hemorrhage
 Stevens-Johnson syndrome
 Stiff-man syndrome
 Still's disease
 Stroke
 Subacute Bacterial Endocarditis
 Subacute multiple-site osteomyelitis
 Subacute organic psychosyndrome
 Subacute multiple-site osteomyelitis
 Subacute presenile dementia
 Subarachnoid hemorrhage
 Sudden deafness
 Sudden hemiparesis
 Sudden infant death syndrome (SIDS)
 Sudeck's atrophy
 Synovitis
 Syphilis
 Symmetric Polyarthrits
 Temporal arteritis
 Temporomandibular joint syndrome
 Thrombocytopenic purpura
 Thyroiditis
 Tourette's syndrome
 Transient Ischemic Attack
 Transient left ventricular dysfunction
 Trigeminal Neuralgia
 Unilateral interstitial keratitis
 Unilateral papillitis
 Urticaria
 Uveitis
 Vasculitic neuropathy
 Vasculitic mononeuritis multiplex
 Vasculitis
 Ventricular asystole
 Vertigo
 Vestibular neuronitis
 Vitreous clouding

UNDERSTANDING THE MECHANISM OF SAMENTO

Toxins and the Immune System

A great deal of global research exists on microbial toxins and the evaluation of their clinical and molecular toxicology on cells. This includes both tissue direct effects and effects on the blood stream (toxinemia). In particular, *Borrelia burgdorferi* (Lyme Borreliosis) toxicant production and its direct effect on cells, tissues and organs, is a highly relevant topic in terms of both a) the mechanism of action and b) showing targets for proposed and potential therapies.

There are reported cases of patients with diseases today known to be Lyme Borreliosis mimics, who have received Samento and have shown remarkable clinical and physical improvement within a period of as little as 24 to 72 hours. These are individuals who have been suffering for years and have been treated with conventional and CAM therapies. The rapid response to this treatment may be assumed to be toxicants blockage – inhibitions more than immune system response or spirochete bactericidal effects in a very short period of time.

Since 1819, when James Parkinson described Parkinson Disease (PD) by stating “No pathologic finding was conclusive to brain specific lesions as the true clue for the origin and evolution of PD”, we have more questions than answers about the etiology of PD and other diseases such as Multiple Sclerosis, Alzheimer and many others. This leads to the reality of NOT having good and effective treatments with no side effects, and more importantly, treatments that control, stop, or reverse these diseases.

Current molecular and clinical toxicology have permitted the introduction of the term “Bio-toxins induced illness”, the most important in this category being Lyme Borreliosis, which is a rapidly-spreading worldwide epidemic.

From the molecular toxicological point of view, as stated by Dr. C. Shoemaker, MD and H. Kenneth Hudnell, PhD, “*Borrelia burgdorferi* produces a large suite of Bio-toxins that have tissue (cells) affinity, mainly NEUROTOXINS with high molecular tropism for lipid structures, i.e., central nervous system (CNS), peripheral nerves, muscles, Joints (Synovial fluid composition and joint cartilage), lungs, and many others. Bb’s Bio-toxins are more cellular than toxinemics (blood stream)”. If this is true, the origin and evolution of, and complications from, chronic degenerative diseases such as PD in young adults is much more understandable. In many cases, autopsies performed on individuals in their early 30’s have not demonstrated the “degenerative process” of basal brain ganglia associated with their diagnosed brain altering diseases.

These deaths seem to have been caused by the introduction of BIO-TOXINS that have altered a specific site (i.e.: neurotransmitters – pre- and post synapses membrane, altered dopamine, serotonin, GABA, acetyl-choline molecules, blocking surface membrane receptors of different kinds, altering molecular normal action of enzymes, co-enzymes and hormones). All of these and many more are widely demonstrated to be the route of action of different Bio-toxins.

Finally, in explaining the lack of energy and fatigue that is almost invariably present in Lyme Borreliosis and in the list of more than 300 illnesses reported to be “related” to Bb’s bio-toxins, one molecular toxicology fact has been correlated. This is that the calcium channels’ normal functioning may be altered by Bb’s neurotoxicants. Therefore those neurotoxins will act on cell

membrane surfaces and receptors, and within the inner cell membrane sub-molecular components, and in the cytosol. There are published reports attesting toxicant effects on cell granules and even at RNA and DNA expressions level.

In conclusion, Samento may have three “modulating” and direct actions on individuals suffering from Lyme Borreliosis and related illnesses:

- The proven Immune System modulator effect
- The proven broad spectrum anti-microbial effect
- The modulating “blocking” effects on the adverse Bio-Neurotoxins molecular actions.

Nonetheless, further research is indispensable in this matter.

How Samento May Eliminate the Pathogen

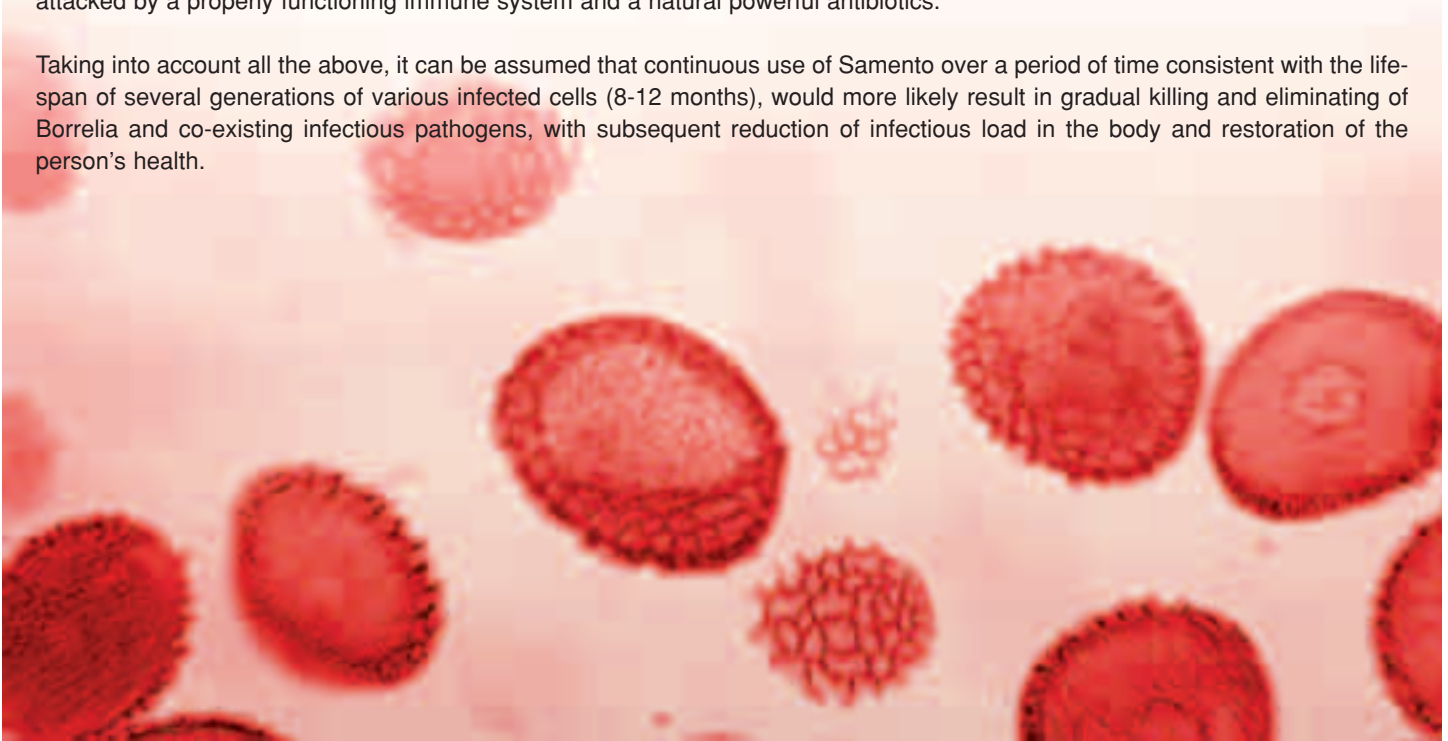

The latest research on *Borrelia burgdorferi* (Bb) shows that it exists in at least three different forms: the spirochete, the spheroplast (also known as L-form), and the cyst form. During the course of infection, Bb can shift among these three forms, converting from the spirochete form to the others when presented with an unfavorable environment (antibiotics, changes in pH of body fluids in chronic inflammation, etc.), and reverting back to the spirochete form to grow and reproduce upon being released from naturally aging and dying infected cells. It is during the growth period after re-conversion to the spirochete form, as well as in adult spirochete form, that Bb is most vulnerable and susceptible to antibiotics and natural elimination by the body's immune system.

The severity of Lyme presentation is directly related to the spirochete load: low load results in mild or even asymptomatic infections. With increased spirochete load from subsequent repeated infections and/or reactivated dormant infections, the severity of the disease increases. Higher loads also impair key cells of the immune system and modify the immune response, thus making the immune system unable to fight the pathogen. The negative effects on the immune system increase the longer the spirochetes are present. To prevail in the effort to fight Lyme disease, it is necessary to not only restore the immune system to normal functioning, but to boost it as well. Even a normal functioning immune system is unable to attack and eliminate Bb in all its forms.

The results of research on Samento (TOA-free Chemotype Cat's Claw) demonstrate its powerful immune system modulating and stimulating properties, along with pronounced anti-inflammatory, antioxidant, and anti-infectious effects. The diverse spectrum of the biological activities of Samento is due to its biologically active compounds. The pentacyclic oxindole alkaloids (POAs) contained in this Chemotype are generally accepted as the principal immunomodulating and immunostimulating agents. POAs are actively involved in the repair of many elements and functional mechanisms of both the innate and acquired immunity damaged by the *Borrelia* and other co-infections, assisting in restoration of structural and functional integrity of the immune system, enhancing its ability to eliminate the pathogens by natural way. In addition, this Chemotype contains quinovic acid glycosides – compounds with strong natural antibiotic properties (the latest generations of conventional synthetic antibiotics “Quinolones” are based on quinovic acid glycosides), which further enhance the medicinal effect of Samento in fighting the infection.

Considering the life-time of intracellular forms of Bb equivalent to the life-span of the cells invaded by these forms, they are constantly released into surrounding environment upon the natural cell death and destruction. The release of intracellular forms of Bb is gradual over the time due to various life-span of various invaded cells. Since about 90% of these forms reside in various cells (including all blood cells) which have the life-span from 2-3 weeks to 6-8 months, it may be assumed that within a 6 to 8 month period, a significant majority of all intracellular form of Bb will be released into the environment where they can be successfully attacked by a properly functioning immune system and a natural powerful antibiotics.

Taking into account all the above, it can be assumed that continuous use of Samento over a period of time consistent with the life-span of several generations of various infected cells (8-12 months), would more likely result in gradual killing and eliminating of *Borrelia* and co-existing infectious pathogens, with subsequent reduction of infectious load in the body and restoration of the person's health.

NEW TEST FOR IDENTIFYING THE MORPHING MENACE

Q-RIBb® *“Quantitative-Rapid Identification of Borrelia Burgdorferi”*

by Dr. Jo Anne Whitaker

Jo Anne Whitaker, M.D., a prominent international medical researcher suffering from Lyme disease and her associates have developed a new method to provide physicians with an accurate quick diagnosis of Lyme disease. Dr. Whitaker has authored over 70 scholarly publications and has accumulated numerous awards and citations throughout her career.

She has had extensive fellowship programs in pediatrics, hematology, oncology, nutrition and psychiatry. She taught in seven different medical schools and retired as a full professor of pediatrics. She spent 9 years in Southeast Asia, starting a new medical school and nutritional laboratory in Thailand and a post-graduate training program in Vietnam during the war. After returning from Vietnam, she was director of the Florida Mental Health Center in Tampa. She helped start and develop the first hospice in Florida and initiated the Little Kids Program for Abused Children at the Chi Chi Rodriguez Children's Program. Because of her personal healing experience and subsequent commitment to the Bowen Technique, she has become a Master Bowen Practitioner and teacher. She established Bowen Research and Training Institute, Inc., a not for profit corporation in 1996 to provide a research and training center for Bowen therapy.

She conducted the first clinical study to identify pathogenic *E. coli* by using the florescent antibody test (FAT) on infant stool specimens at a children's hospital in Detroit in 1956. She adapted the methodology to identify beta hemolytic strep disease, diphtheria and pertussis. Also using the FAT she was

instrumental in developing an anti nuclear antibody test for lupus; a method for blood and parasitic antigens and tumor markers. Now some 40 years later Dr. Whitaker has found this technique to be applicable in identifying the causative agent of Lyme disease.

LYME DISEASE

Lyme disease is called the “New Great Imitator” because, like syphilis, it attacks multiple organ systems and mimics many diseases. Both diseases are caused by a spirochete. Lyme disease is caused by *Borrelia burgdorferi* (Bb), an elongated spiral shaped bacterium that infects humans and animals. Bb, previously thought to be transmitted only by the deer tick (*Ixodes dammini*) is now recognized to be transmitted by fleas, mosquitoes and mites. There is more compelling evidence to support sexual and congenital transfer and even more recently it has been identified as a food infection.

If ignored, the early symptoms may disappear but more serious problems can develop months to years later. The later symptoms of Lyme disease can be quite severe and chronic. Muscle pain and arthritis, usually of the large joints is common. Neurological symptoms include cognitive impairment, memory loss, depression, numbness, tingling, and burning sensations in the extremities, Bell's palsy, severe pain and fatigue. Involvement of all systems such as cardiac, ophthalmic, respiratory and gastrointestinal problems can develop. Miscarriage, premature births, stillbirths, birth defects and transplacental infection of the fetus have been reported. Symptoms are often intermittent lasting from a few days to several months and sometimes years. Chronic Lyme disease, because of its diverse symptoms, mimics many other diseases and can be difficult to diagnose.

TREATMENT

Successful management and treatment of Lyme disease rests on early and accurate diagnosis. Timely treatment increases chances of recovery and may lessen the severity of any later symptoms. The most effective treatment will depend on the stage of the disease. Treatment for later stages is more difficult often requiring extended and repeated courses of antibiotic therapy and a holistic approach to therapy. The diagnostic tests now being used for Lyme disease are neither sensitive nor specific and consequently results are not reliable.

It is well known that the serologic blood test for Lyme is insensitive, inaccurate and misses over 40 percent of cases. It is important to understand the nature of the Bb organism. Bb can change its shape from a spiral to a filament, cyst, granule, hooked rod or elbow. These variants are called L-forms, a name given by the Lister Institute where they were first studied. These L-forms are

**Borrelia
burgdorferi
spirochete**

also called cell-wall deficient (CWD) bacteria taking the non-spiral shape when they have lost much of the cell wall. In this form they do not produce an antibody response, as they have no cell wall for the individual's immune system to respond to. Classic L-forms are active metabolism centers for the production of CWD pleomorphic organisms (Bb). In this form they are able to hide within most tissues in the body, thus protecting them from any host response adverse to their well-being. CWD organisms can revert to typical morphology and may revert into adult forms of other genera, depending on the milieu. For this reason most of the diagnostic tests, i.e. ELISA and Western Blot, which depend on the production of antibodies, are inadequate. Much like the hepatitis model, antigen is present early after initial infection. Later there is an antibody response in about 70% of patients. Tests that look for antibody response will not support an early diagnosis, nor reliably confirm presence of the disease.

BOWEN RESEARCH & TRAINING

After learning about the Bowen Technique and experiencing how this simple gentle therapy relieved so many of my symptoms, I established Bowen Research & Training Institute primarily to research how the Bowen Technique affects the body. Bowen Therapy is a gentle non-invasive body therapy that seems to bring the autonomic nervous system into balance. I was investigating the effect of the Bowen Technique on the autonomic nervous system (ANS) in patients diagnosed with Fibromyalgia, it was noted that soon after the Bowen therapy, some patients developed flu-like symptoms. Dr. Lida Mattman, who has been culturing cell wall deficient (CWD) organisms from blood for 40 years was contacted to culture specimens from 25 individuals diagnosed with

Fibromyalgia Syndrome. She found every sample positive for CWD *Borrelia burgdorferi*, the causative organism of Lyme disease.

Following this finding 103 seriously ill subjects with a variety of diagnoses were tested and found to be positive for Bb based on Mattman's Gold Standard Culture method. The conditions included: Fibromyalgia, Osteoarthritis, Mixed Connective Tissue Diseases, Polymyalgia Rheumatica, Ankylosing Spondylitis, Lupus Erythematosus, Palindromic Rheumatism, Chronic Fatigue Syndrome, Multiple Sclerosis, and Amyotrophic Lateral Sclerosis. I was shocked as I was one of that group (my diagnosis at the time was Polymyalgia Rheumatica).

As I tried to come to grips with this finding—that I might have Lyme disease, I thought about my childhood. When did this all start? I grew up in Polk County, Florida and as a kid I spent a lot of time in the woods and had numerous tick bites. I was never diagnosed with any particular malady in my childhood and I never had an EM rash. As a young adult I had bouts of multiple muscle and joint aches and pains but was able to function. I finished high school in 3 years and went on to college at USF and later to medical school at Wake Forrester in Winston Salem, NC. I was very athletic in my youth and won the Florida State Amateur Golf Championship in 1948 and again in 1952. I loved golf but because of my profession never had much time to play.

I recall having periodic muscle and joint aches and pains throughout my life receiving a variety of diagnoses, —Rheumatoid arthritis, Lupus, and Polymyositis Rheumatica. Because of my strong constitution I continued to live a productive life.

For the past six to seven years I have had severe muscle and joint pain and, in retrospect, these symptoms started around the

time I saw continuous changes in my number 18 left lower molar. This tooth was extracted January 2000 and contents tested positive for cell wall deficient (CWD) *Borrelia burgdorferi* (Bb) by the RIBb test and Mattman culture.

During the development of the RIBb test my blood was examined and was positive! I did not believe it. To my surprise the usual negative antibody tests were also all positive including a Lyme Urine Antigen Test (LUAT), which was exceptionally high (over 400). There was no doubt about it. I had Lyme disease and have probably had it since a little girl when I had many tick bites on hunting outings. At that time I was aware that my symptoms were becoming more intense. I had many neurological symptoms—brain fog, short-term memory loss and stiff neck; night sweats, alternating feeling hot and then feeling cold I had extreme hypersensitivity to light, sound and odors. I started wearing dark glasses even inside. I had very little energy, I was easily fatigued, and often had a sore throat. It was very difficult for me to work, I could not last more than an hour or two and even then I was “not worth much”. I began to search for more information on this nonspecific disease and found that I was not atypical. My case was most likely chronic. Finally I was convinced that I did indeed have Lyme disease, so what was I to do about it. It was difficult to find a physician locally to treat my condition. I contacted several known specialists in Lyme disease and one advised me to go on long-term doxycycline, which I did. I also discovered a host of alternative therapies, which I have tried. I have experienced an improvement in many of the symptoms from regular Bowen Therapy treatments. I have tried numerous herbal and nutritional supplements; many have helped and some have not over the long term.

Since discovering that I did indeed have Lyme disease, I have been more or less on continuous antibiotic therapy.

DEVELOPING A NEW TEST

After finding that there were few accurate tests for *Borrelia burgdorferi* (Bb), my colleague Eleanor Fort, a medical laboratory technologist, with a long history of research involvement in pediatric hematology/oncology and I, at Bowen Research and Training, developed a Rapid identification profile (RIBb©) for this organism. The method uses a fluorescent antibody technique on whole blood and is noteworthy for sensitivity and for the brief time required to complete the test, less than 60 minutes. The accuracy of this method was tested in two other laboratories with identical results. In addition we look at a concentrated suspension of red and white blood cells (rather than a routine blood smear) to identify the co-infections associated with Lyme disease (*Ehrlichia* in the white blood cell and the parasite *Babesia*, in the red blood cell). Occasionally we see all three infections in the same individual—Bb, *Ehrlichia*, and *Babesia*. All of these patients have definite abnormal peripheral red blood cell morphology. This is noteworthy, as all require different treatment.

The RIBb test has been further refined. We are currently doing Quantative Rapid Identification of *Borrelia Burgdorferi* Q-RIBb©. This process provides a quantitative titration (serial dilution) method of detecting the antigen in a fluid sample of a subject. The test is considered positive for Lyme disease upon detection of brightly fluorescent antigen-antibody complexes. Antibiotics do not affect the test so it is effective whether or not the person being tested is on antibiotics. When observed in phase contrast, the L-forms can be described morphologically. A preliminary report of the findings is provided within 24 hours of receiving the specimen and the final report includes digital

Specific Fluorescence of a Cell Wall deficient *Borrelia burgdorferi* bacteria.

Phase contrast image of the same cell showing *Borrelia burgdorferi*.

photographs of the findings. This test is useful in evaluating treatment by comparing pre and post serial dilution results.

We have now tested over 3500 specimens, with 500 of these very sick children, from a wide geographical distribution as previously described, and all are positive for cell wall deficient Lyme disease. The primary question is “why are there no negatives?” Does everyone have it? While the majority of our specimens come from individuals who have been diagnosed clinically, we have tested individuals who we “thought” were asymptomatic but were positive for the Bb. An interesting finding is that in 1995, Mattman found forty-three of forty-seven (43/47) patients with chronic diseases to be positive for Lyme disease, while twenty-three of twenty-two (22/23) control cultures were negative. Since 1999, all blood cultures have been positive with Bb, there were no negatives. We believe this indicates the magnitude of the problem. The CDC is now reporting that Lyme disease is more widespread than earlier thought. We believe the problem is not only endemic but may also be reaching epidemic proportions. Early diagnosis is mandatory so that treatment can begin immediately to provide opportunity for cure and prevent chronic Lyme disease.

EXAMPLES OF MISDIAGNOSIS

The following stories of 4 individuals with diagnosis of ALS illustrate how important early diagnosis is.

THE FIRST is an individual with a 10-year diagnosis of ALS from whom we received a spinal fluid and blood specimen. The spinal fluid was highly positive for Bb, as was the blood. We reported the findings within a 24-hour period of receiving the specimens only to learn that the individual had died.

THE SECOND individual also had a long history of problems identified as ALS. His RIBb test was positive and he was not able to get any physician to treat him for Lyme disease. His health deteriorated and he was admitted to a hospital and was on life support. When his wife was told of his impending death she obtained a court order to have him treated with antibiotic therapy for Lyme disease. He recovered enough to get off life support and was subsequently discharged. He gained weight (32 pounds) and lived eight more months and then died of a heart attack.

THE THIRD individual is a 25-year-old golfer on a golf team. He became very ill and was unable to play golf. He was diagnosed with ALS. A family friend knew about our test and sent a blood specimen to be tested for Lyme disease. The results were positive. He was started on appropriate antibiotic therapy and was soon able to resume his golf career. He is now a professional golfer. Having an early diagnosis seems to have made the difference for this young man in living a productive active life.

THE FOURTH is a young college student who began having cognitive difficulties and had to drop out of school. He learned about our laboratory and was tested and found to be positive for Lyme disease. After four months on antibiotic he was able to resume his normal active life and is on the deans list and writing classical music.

These examples may shed some light on the importance of early diagnosis and appropriate treatment for Lyme disease. Left untreated the out-come of Lyme disease can result in a chronic debilitating condition and possible death. Are you sure you don't have Lyme disease? Use RIBb for life.

Samento approved as a medicine in Ecuador

In September, the Health Department of Ecuador approved Samento as a medicine. Physicians are now prescribing Samento for their patients.

AVAILABLE SOON AT YOUR LOCAL PHARMACY

Registro Sanitario 045-MNE-08-03

Coming soon...

Potent Samento Extract

A Proprietary Extraction and Enhancement Process!

**A 1 ounce bottle of Samento Extract (48 USD)
equal to 20 bottles of capsules (800 USD).**

94% LESS EXPENSIVE!
